Predicting House Prices in Ames, Iowa

Machine Learning Project

Background

- Kaggle dataset with 79 explanatory variables describing homes in Ames, Iowa (home of Neva Morris, the oldest living person in the US until 2010)
- Objective is to fit a machine learning model that will best predict 1,459 house prices and identify the most important features for these predictions

Outline

Exploratory Data Analysis

 Data visualization to identify trends and prepare for data cleaning

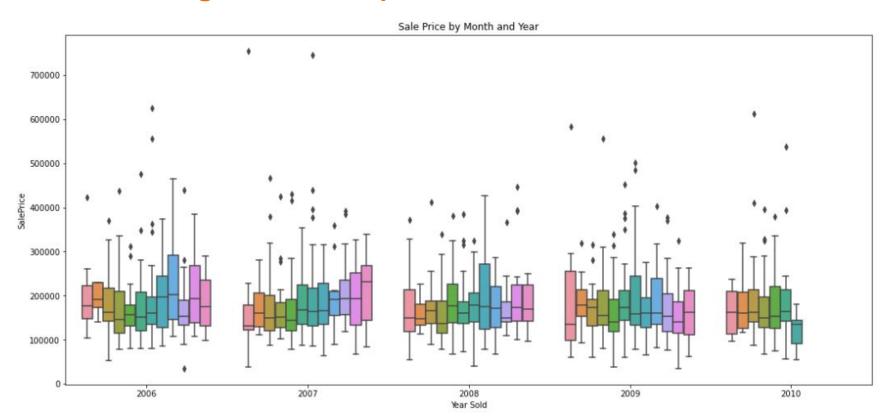

Data Cleaning & Pre-Processing

- Imputing missing values
- Feature selection/ de-selection
- Feature engineering

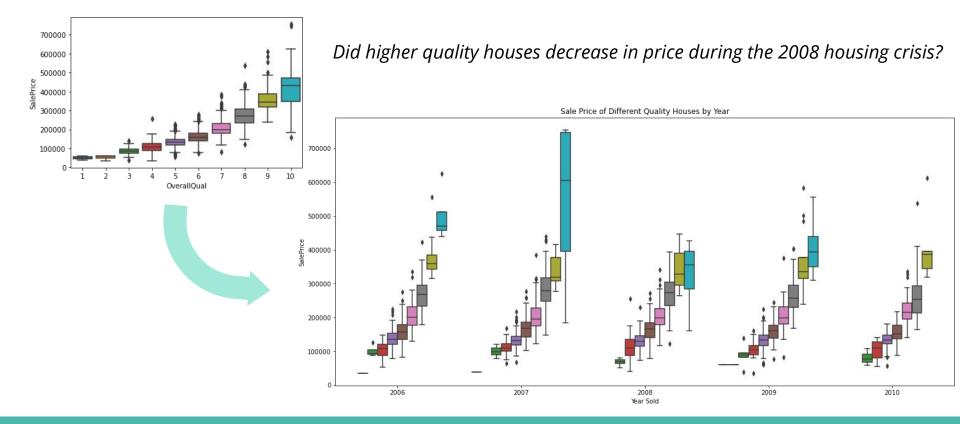

Model Fitting & Evaluation

Comparing RMSE
across models to
determine the best
fit for final
predictions

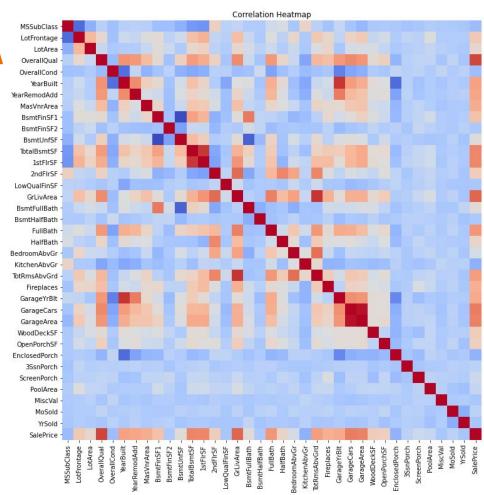

EDA- Pricing Seasonality

EDA- Sale Price & Overall Quality

EDA

 Drop GarageCars since it's highly correlated with GarageArea

 Drop GarageYrBuilt since it correlates highly with YearBuilt

 Drop TotRmsAbvGrd (corr to GrLivArea)

 Drop 1stFISF + 2ndFISf because of GrLivArea and the close correlation between basement and first floor sq ft

--0.2

- 0.8

- 0.6

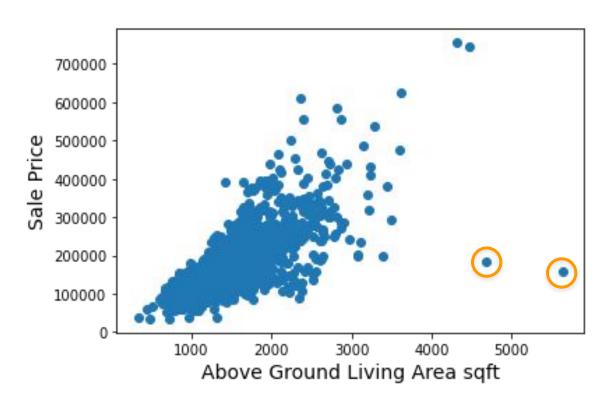

-04

- 0.2

- -0.4

Data Cleaning- Eliminating Outliers

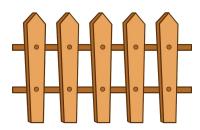

Data Cleaning- Imputing Missing Values

Missing values for 20 out of 29 columns were related to non-essential, or "bonus" home features and easily imputed with zero or "none"

Data Cleaning- Imputing Missing Values

- Missing values for 7 categorical columns were imputed with the mode
- **LotFrontage** (16.7% missingness) was imputed with neighborhood mode
- **Utilities** was dropped, as all values were the same except for one in the train dataset

Feature Engineering- New Variables

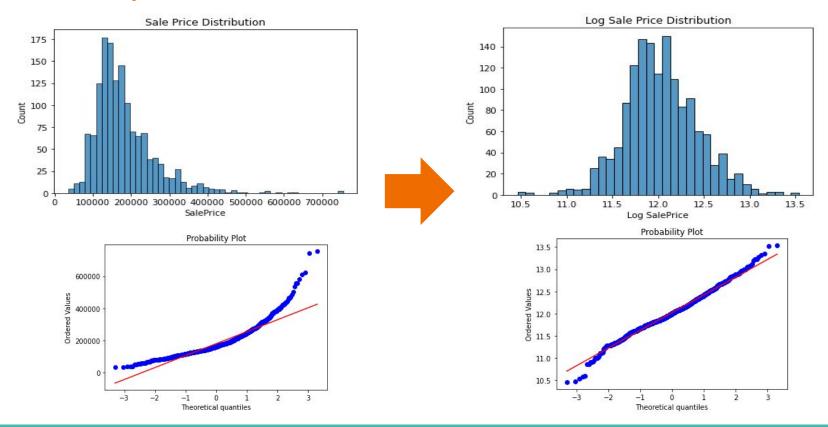

- HouseAge was calculated from YearSold and YearBuilt to replace YearBuilt
- YearsSinceRemod was calculated to replace YearRemodAdd
- TotalBathrooms was calculated to consolidate basement and non-basement full bath and half bath variables
- PorchSF was calculated to consolidate the square footage of various porch types
- MSSubClass, MoSold (month), and YearSold were changed from numeric to categorical

Encoding Categorical Variables

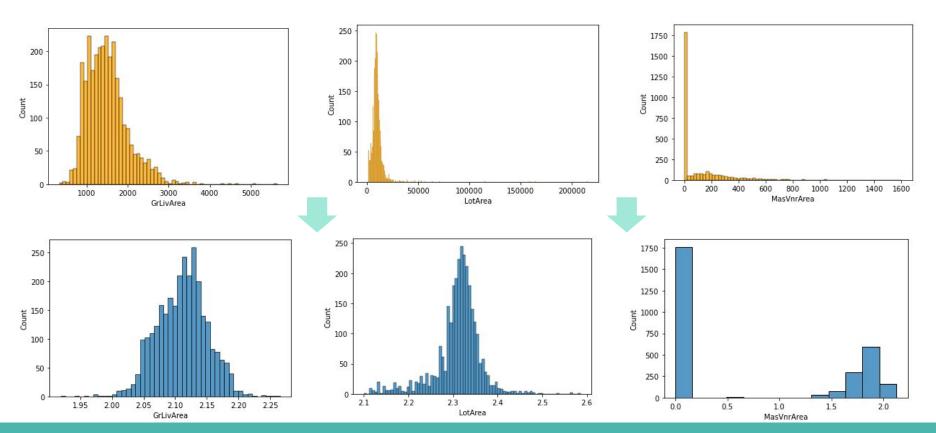

- Ordinal Encoding was used to encode 14 categorical variables, such as for various quality scores
- Non-ordinal categorical variables were dummified for linear models

EDA- Dependent Variable

Log Transformation of Highly Skewed Variables

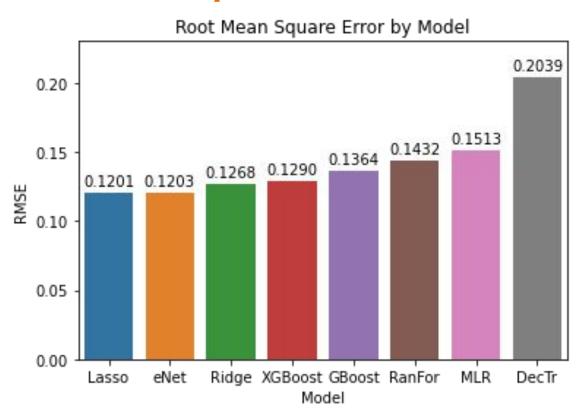

Model Fitting & Evaluation

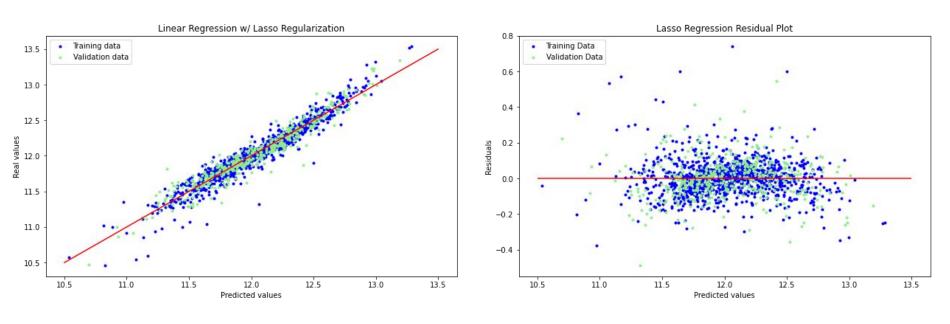

- Multiple linear regression
- Penalized linear regression
 - Ridge
 - Lasso
 - Elastic Net
- Decision Tree
- Random Forest
- Gradient Boost
- XGBoost

Model Comparison

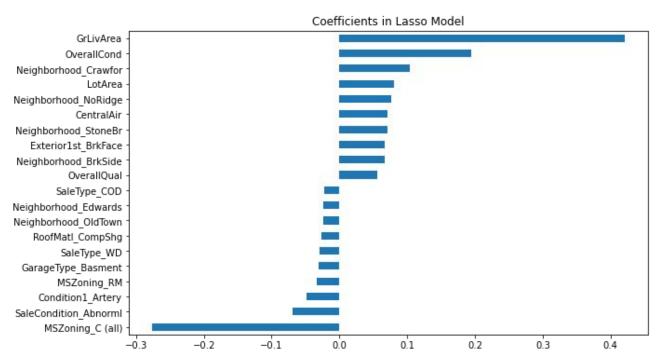

- Data was split into train and test sets and evaluated 10-fold cross validation
- Lasso penalized linear regression delivered the lowest RMSE
- XGBoost was the highest performing non-linear model; however its RMSE was still higher than the penalized linear models after using a grid search to tune parameters

Lasso Model- Prediction Plot & Residuals

Visually, the regression seems to be a good fit and the residuals are randomly distributed around the center line with no clear pattern

Lasso Model- Top Coefficients

- Above ground living area is the most significant predictor of sale price, followed by overall condition
- Six of the top coefficients relate to **neighborhood**. Houses in Crawford tend to be the most expensive
- Commercial zoning classification was the top negative coefficient followed by an abnormal sale condition indicating a trade, foreclosure, or short sale

Key Takeaways

- A bigger house is not always a better house, but in Ames it is most likely a more expensive house
 - Home owners can significantly increase the value of their home through constructing home extensions, when possible
- Home buyers looking to save money on a nicer house should consider neighborhoods like Edwards and Old Town
- And finally, indecisiveness is a tough trait to have when it comes to machine learning

Opportunities for Further Analysis

- The final predictions scored in the top 25th percentile on Kaggle. Given additional time and resources, fine tuning some of the model parameters may provide better results as we find an ideal balance between overfitting and underfitting
- We may also try blending or stacking some of the models, although this approach will add a layer of complication and make the model more difficult to interpret
- Testing out different adjustments to feature engineering, such as binning categorical variables (neighborhood, month sold) or performing different transformations of skewed variables with may also improve the model predictions
